

# CarPi

by Nicole Alvarado (35983), Jonathan Stuermlinger (34602), & Ben Koellner (34603)

## Introduction

For our AMC project, we developed a basic traffic monitoring system using a Raspberry Pi 5, designed to detect and count vehicles as they pass through a designated section of road captured by a camera. The collected data is uploaded to a web-based dashboard, which could provide a foundation for traffic flow analysis and supporting studies on air pollution, noise levels, and overall urban livability. Such information can also play a valuable role in infrastructure planning and broader environmental monitoring initiatives.

## Material & Methods

### Hardware Components

The project was developed using the following hardware components:

- Raspberry Pi 5
- Raspberry Pi High Quality Camera (CS Mount)
- MicroSD card (32 GB)
- Power supply
- HDMI cable
- Monitor
- Mouse and keyboard

### Hardware Assemblance

To prepare the hardware environment for traffic monitoring, the Raspberry Pi 5 was assembled to create a functional and interactive environment for real-time object detection. The hardware integration process is as followed:

Fig. 1: System Build

1. Insert the camera's ribbon cable into the CSI (Camera Serial Interface) port of the Raspberry Pi by lifting the plastic latch and pressing back down to secure the cable.
2. Screw the CS-mount lens onto the HQ camera board and attach the other side of the camera's ribbon cable.
3. Connect the USB keyboard and USB mouse into the USB ports of the Raspberry Pi.
4. Connect the monitor using an HDMI to micro-HDMI cable.
5. Once flashed, insert the 32 GB microSD card.
6. Plug in the USC-C power supply to the Raspberry Pi's power port, this will automatically boot the system.
7. Mount the camera in a fixed position using a tripod facing the desired street area.

## System Setup

### Raspberry Pi Initialization

The Raspberry Pi 5 was set up using a flashed MicroSD card containing the latest version of Raspberry Pi OS (64-bit). This was done via the Raspberry Pi Imager by selecting:

- Device: Raspberry Pi 5
- Operating System: Raspberry Pi Os (64-bit).
- Storage: 32 GB MicroSD card.

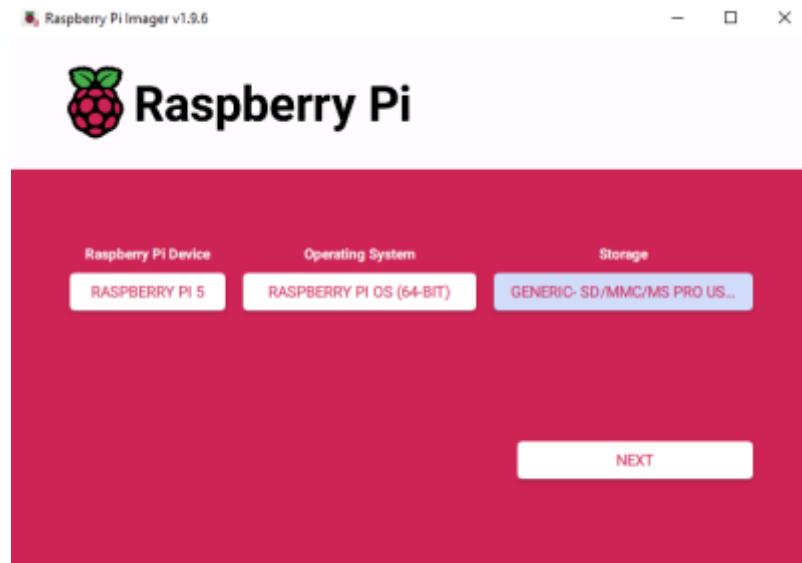

Fig. 2

## Installing OpenCV and Required Packages

To enable object detection, OpenCV version 4.8.1 was compiled. The following commands were executed on the Raspberry Pi terminal:

```
sudo apt-get update && sudo apt-get upgrade
sudo nano /etc/dphys-swapfile
```

Essential libraries and tools were installed:

```
sudo apt-get install -y \
build-essential cmake pkg-config \
libjpeg-dev libtiff-dev libpng-dev \
libavcodec-dev libavformat-dev libswscale-dev libv4l-dev \
libxvidcore-dev libx264-dev \
libgtk-3-dev \
libatlas-base-dev gfortran \
python3-dev python3-numpy python3-pip \
python3-picamera2 python3-opencv
```

OpenCV library and its additional modules were retrieved from Github, unzipped, and set up for the build process:

```
cd ~
wget -O opencv.zip https://github.com/opencv/opencv/archive/4.8.1.zip
wget -O opencv_contrib.zip
https://github.com/opencv/opencv_contrib/archive/4.8.1.zip

unzip opencv.zip
unzip opencv_contrib.zip

mv opencv-4.8.1 opencv
mv opencv_contrib-4.8.1 opencv_contrib
```

Compilation and installation of OpenCV performed as follows:

```
cd ~/opencv/
mkdir build
cd build

cmake -D CMAKE_BUILD_TYPE=RELEASE \
      -D CMAKE_INSTALL_PREFIX=/usr/local \
      -D INSTALL_PYTHON_EXAMPLES=ON \
      -D OPENCV_EXTRA_MODULES_PATH=~/opencv_contrib/modules \
      -D BUILD_EXAMPLES=ON ..

make -j$(nproc)
sudo make install
sudo ldconfig
```

## Creating a Python Virtual Environment for the dashboard

To prevent conflicts with the system's main Python package repository, the dashboard was developed within a virtual environment to manage its required packages independently.

```
sudo apt install python3-venv python3-full
python3 -m venv ~/dashboard-env
source ~/dashboard-env/bin/activate
pip install flask pandas plotly
```

## Files Setup and Execution

Provided below is a downloadable ZIP containing the pre-trained COCO object detection model used in this setup. It also includes a list of all detectable object classes that the COCO library has been trained to recognize. All project files, including the object detection, dashboard scripts and vehicle log, were placed into the previously downloaded archives (Object\_Detection\_Files) and transferred to the Raspberry Pi Desktop using a USB stick.

object\_detection\_files.zip

To execute the object detection script, enter the following command in the terminal.

```
cd /home/pi/Desktop/Object_Detection_Files
python3 object_detection_final.py
```

Once the detection process is running, you can launch the live dashboard by activating the virtual environment and starting the server. The dashboard can then be accessed via a web browser using the address shown in the terminal.

```
source ~/dashboard-env/bin/activate
cd /home/pi/Desktop/Object_Detection_Files
```

```
python dashboard.py
```

## Results

### Code

Three Python scripts were developed as part of the system's functionality.

1. Object Detection
2. Vehicle Log
3. Dashboard

The object detection script (object\_detection\_final.py) uses OpenCV's DNN module with a pre-trained SSD MobileNet model trained on the COCO dataset. It captures video input from the Pi camera, identifies vehicles (car, bus, truck, motorbike), draws bounding boxes, and logs the counts into a CSV file.

```

The vehicle\_log.csv serves as the system's central data log for vehicle detection events. It is automatically generated and updated by the object detection script each time a vehicle is recognized in the camera feed. Each entry in the file consists of a timestamp, the type of vehicle detected (e.g., car, bus, truck, motorbike), and a numeric count (typically per detection). This log acts as the primary data source for the dashboard script, which reads and processes it in real time to generate visualizations. The file is stored locally in the same directory as the scripts and can be reset via the dashboard interface to clear all logged entries. The log of the data looks like this:

```

2025-07-28T16:04:24.174465,car,14
2025-07-28T16:04:27.597785,car,15

## Discussion & Conclusion

While our traffic monitoring system functions reliably in its current form, there were several lessons learned throughout the project. Initially, our goal was to develop the system using the Raspberry Pi 5 in combination with an AI Hat (an additional Raspberry Pi module designed to enhance computing performance) and the YOLO algorithm for advanced object detection. However, due to repeated compatibility and setup issues, we were unable to make the AI Hat fully operational and instead opted for an alternative approach based on OpenCV and COCO (Common Objects in Context) libraries. An important takeaway from this experience is that a more successful integration of the AI Hat and YOLO

framework would likely have required reaching out for external support early on, especially to better understand the specific requirements and limitations of the Raspberry Pi 5 and the AI Hat. Despite these challenges, the alternative solution we implemented proved to be a solid and functional approach for basic vehicle detection and counting.

However, the system is not without limitations. For example, detecting larger vehicles such as buses proved inconsistent, especially depending on the camera angle and environmental conditions. In our case, the monitoring frame was set up between trees, which occasionally interfered with object detection.

Beyond technical issues, permanent deployment of such a system would also require consideration of legal aspects, such as regulations around filming public roads and ensuring privacy compliance.

Currently, the system logs data locally, and access is limited to devices on the same network. A long-term implementation would require modifications to reset the vehicle count periodically (e.g., every 5 minutes or more frequently during peak hours) and to store the data in a publicly accessible database. Data visualization could be improved once sufficient data is collected for meaningful analysis.

Despite these challenges, the project demonstrates that a low-cost and accessible traffic monitoring solution is possible without specialized AI hardware. With further development, such a system could be adapted for real-world use cases in traffic analysis, planning, or environmental studies.
