Schematics

Code & Description

```
*/Reading of voltage is done by the Analog Pin reader.
*/Because the max input voltage on the pins is 3.3 V we cant directly read the 9V battery voltage.

int potPin = A0;           // Analog pin has to be ADC 1, because ADC 2 are
used by wifi and wont work
int potValue;
float voltage =0;          // float because its a decimal number not integer
float battery_percent;

void setup() {

    Serial.begin(115200);

    {

        potValue = analogRead(potPin);
        float voltage = (3.3/4095.0) * potValue * 2.73;

        */Resistors and other components can have a varying number of outputs,
although they are usually minimal
        */additional calibration has to be done in order to get accurate readings
        */We have found that the use of a multimeter will help in determining the
values that will provide best outcomes
        */Because we have different boards, resistors and setups, the final code
could have alterations in the calibrating numbers

        Serial.print("potValue:");
        Serial.print(potValue);

        */While the serial monitor output can be changed, we are more interested is
```

in the overall result which is transmitted

**/to Grafana for easy access*

```
Serial.print(" Voltage:");
Serial.print(voltage);
Serial.println("V");
```

battery_percent = mapfloat(voltage, 3.0, 9.0, 0 , 100); // min value cut off at 6V and maximum voltage is 9V

```
if (battery_percent > 100)
{
    battery_percent = 100;
}
if (battery_percent < 0)
{
    battery_percent = 0;
}
```

**/For the conversion between the actual Analog reading to a percentage we use a mapFloat function*

**/It uses the input range from the analog sensor to produce another set of useful values*

**/float values will allows to get decimal numbers and a more accurate reading*

**/We use a the min voltage value, then max voltage value, and min percentage and max percentage*

**/Then we ask the program to give us the corresponding percentage value within the parameters*

```
Serial.print("Battery Percentage = ");
Serial.println(battery_percent);
```

if (voltage > 7.0 && voltage < 8.2)
CHANGE ACCORDING TO SOURCE

```
{Serial.print("Low bat");
THE ACCURATE VOLTAGE
}
```

if (voltage <6.5)
according to specification , we use 6V

```
{Serial.print("Replace Battery");
}
delay(1000);
```

// THIS VALUES HAVE TO

// USE VOLTMETER TO FIND

//cut-off value is at 5.4V

```
*/We have included a notification that will tell us what is going on with  
the voltage and overall battery status  
*/We include a parameter that will produce 2 warning signs:  
*/ LOW BAT means that our battery is within 7 to 8.2V  
*/ REPLACE BATTERY means voltage has dropped below 6.5V, number obtained  
from data sheet  
  
}  
}  
  
float mapfloat(float x, float in_min, float in_max, float out_min, float  
out_max)  
{  
    return (x - in_min) * (out_max - out_min) / (in_max - in_min) + out_min;  
}  
  
*/here we include the parameters and equation that will serve as the  
backbone for the mapFloat function above.  
  
void loop()  
{  
  
}  
  
*/ NO LOOP NEEDED,,, ONE VALUE WITH WARNING SHOULD BE DISPLAYED ON GRAFANA
```

Issues & Characteristics

The actual voltage will not be 100% accurate because the ADC pins have a non-linear behavior. This means according to the Figure # down below that, above a certain threshold the reading will produce equal inputs, thus we consider that from 3 to 3.3V the battery is at a 100% charge.

Additionally we can see that the discharge behavior of the battery we are using, which is a model 6F22 is a curve that has a specific equation, we could find the curve's equation and use it to better represent the discharge values, however since we plan to upgrade our battery system we purposely used a simpler version in our code to achieve good enough results.

■ Typical Discharge Curve

6F22
